

LOW DROPOUT VOLTAGE REGULATOR

■ GENERAL DESCRIPTION

The NJM2837 is a 1A output low dropout voltage regulator. This product has Reverse Current Protection without external SBD

Advanced Bipolar technology achieves low noise, high ripple rejection and high supply voltage.

2.4V to 15V output voltage range, 2.2 μ F small decoupling capacitor, built-in noise bypass capacitor make the NJM2837 suitable for various applications.

■ PACKAGE OUTLINE

NJM2837DL3

■ FEATURES

- Output voltage options available 2.4 to 15.0V
- High Ripple Rejection 80dB typ. (f=1kHz, V_O=3V Version)
- Output Noise Voltage V_{no}=45 μ V_{rms} typ.
- Output capacitor with 2.2 μ F ceramic capacitor (V_O≥5.1V)
- Output Current I_O(max.)=1A
- High Precision Output V_O±1.0%
- Low Dropout Voltage 0.2V typ. (I_O=600mA)
- Internal Thermal Overload Protection
- Internal Over Current Protection
- Bipolar Technology
- Package Outline TO-252-5

■ TEST CIRCUIT

(*2) 2.9V < V_{OS} ≤ 5.0V version: C_o = 4.7µF (ceramic)
 V_{OS} ≤ 2.9V version: C_o = 10µF (ceramic)

■ TYPICAL APPLICATION

① In the case where ON/OFF Control is not required:

(*3) 2.9V < V_{OS} ≤ 5.0V version: C_o = 4.7µF
 V_{OS} ≤ 2.9V version: C_o = 10µF

Connect control terminal to V_{IN} terminal

② In use of ON/OFF CONTROL:

(*3) 2.9V < V_{OS} ≤ 5.0V version: C_o = 4.7µF
 V_{OS} ≤ 2.9V version: C_o = 10µF

State of control terminal: "H" → output is enabled. "L" or "open" → output is disabled.

***Input Capacitance C_{IN}**

Input Capacitance C_{IN} is required to prevent oscillation and reduce power supply ripple for applications with high power supply impedance or a long power supply line.

You should use the C_{IN} value of 0.1 μ F larger to avoid the problem.

C_{IN} should connect between GND and V_{IN} as short as possible.

***In the case of using a resistance "R" between V_{IN} and control.**

The current flow into the control terminal while the IC is ON state (I_{CONT}) can be reduced when a pull up resistance "R" is inserted between V_{IN} and the control terminal.

The minimum control voltage for ON state ($V_{CONT(ON)}$) is increased due to the voltage drop caused by I_{CONT} and the resistance "R". The I_{CONT} is temperature dependence as shown in the "Control Current vs. Temperature" characteristics. Therefore, the resistance "R" should be carefully selected to ensure the control voltage exceeds the $V_{CONT(ON)}$ over the required temperature range.

***Output Capacitance C_O**

Output capacitor (C_O) will be required for a phase compensation of the internal error amplifier.

The capacitance and the equivalent series resistance (ESR) influence to stable operation of the regulator.

This product is designed to work with a low ESR capacitor (C_O). However use of recommended capacitance or larger value is effective for stable operation.

Use of a smaller C_O may cause excess output noise or oscillation of the regulator due to lack of the phase compensation.

Therefore use C_O with the recommended capacitance or larger value and connect between V_O terminal and GND terminal with shortest path. The recommended capacitance depends on the output voltage rank. Low voltage regulator requires larger value C_O . Thus, check the recommended capacitance for each output voltage rank.

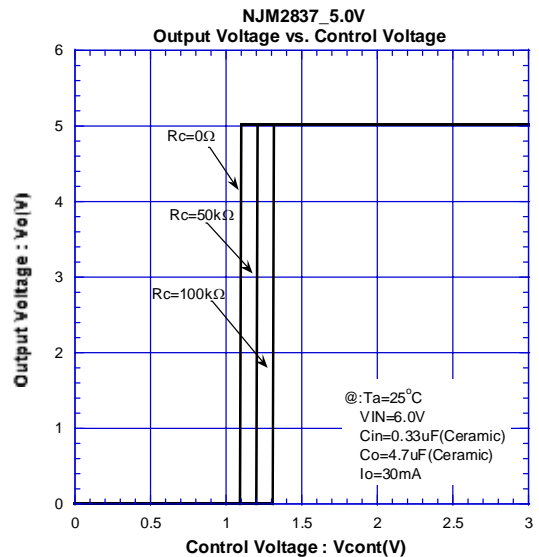

Use of a larger C_O reduces output noise and ripple output, and also improves output transient response against rapid load change.

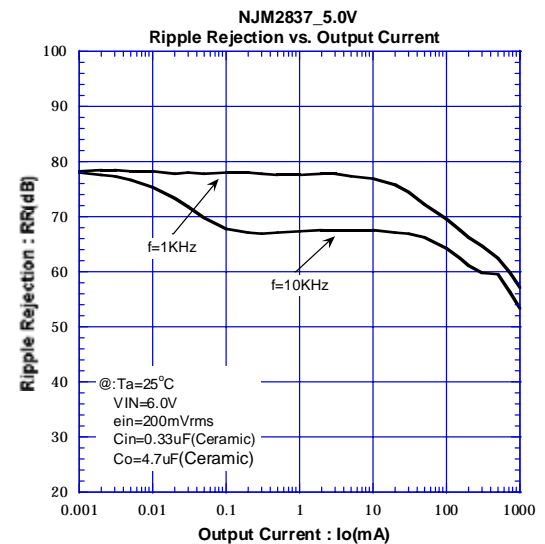

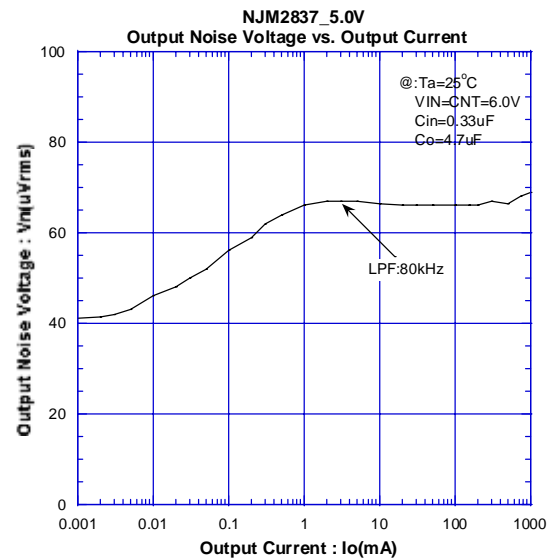

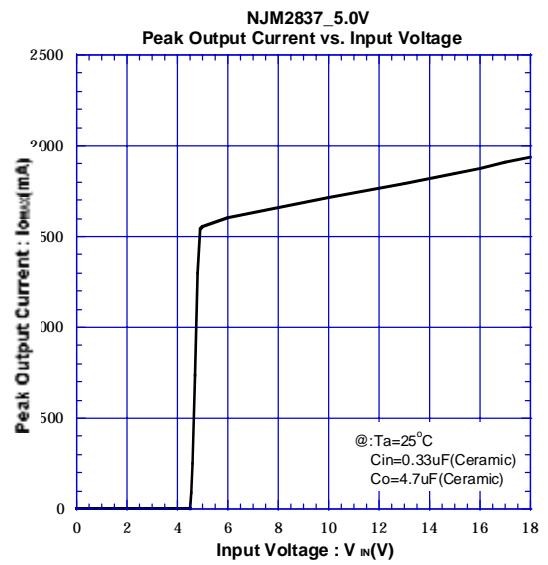

***Reverse Current Protection**

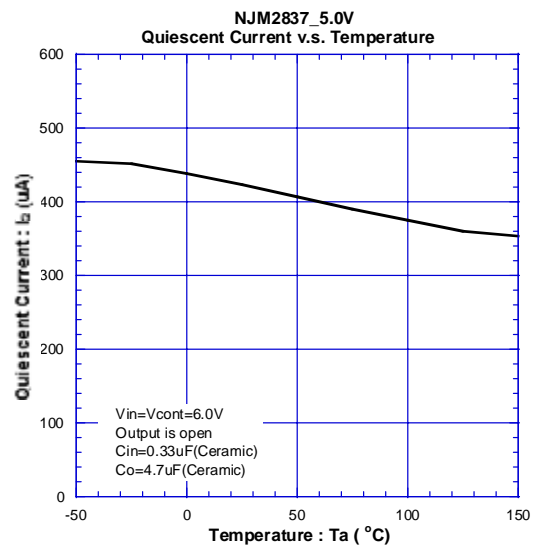

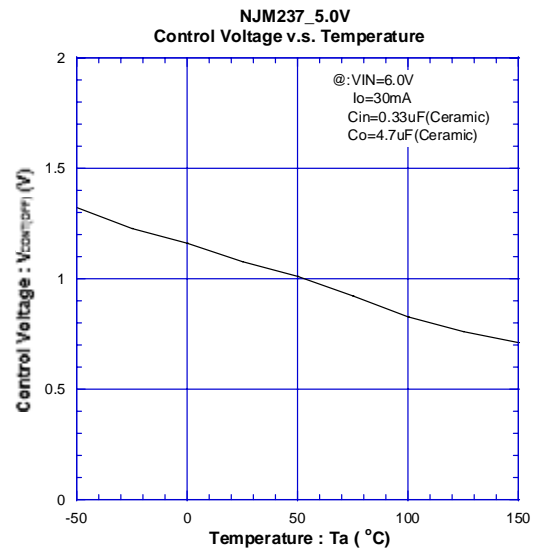

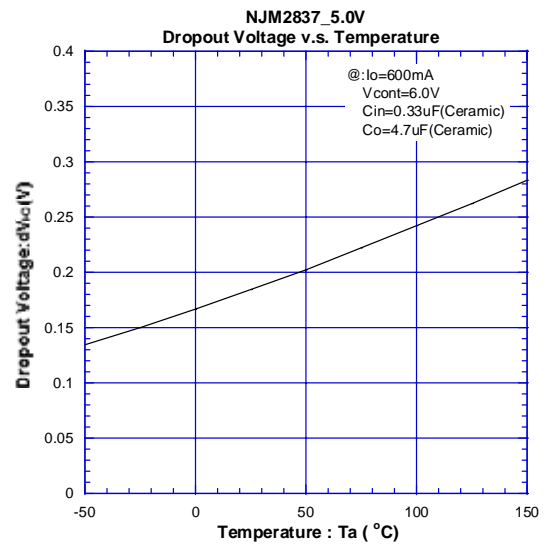

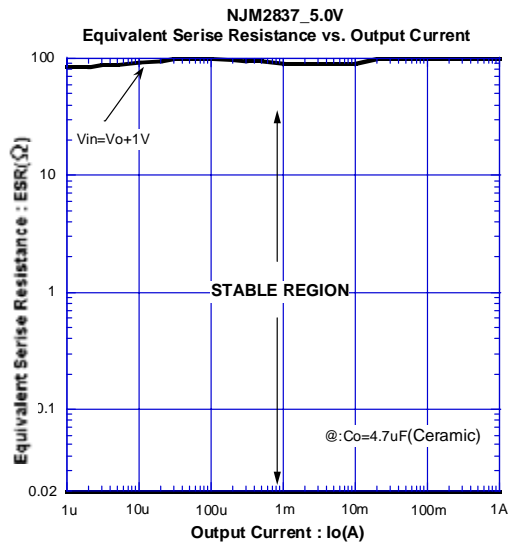

A reverse current protection circuit is built-in to this product and prevents a current inflow from an Output terminal to the Input terminal when the input terminal voltage became lower than the output terminal voltage.

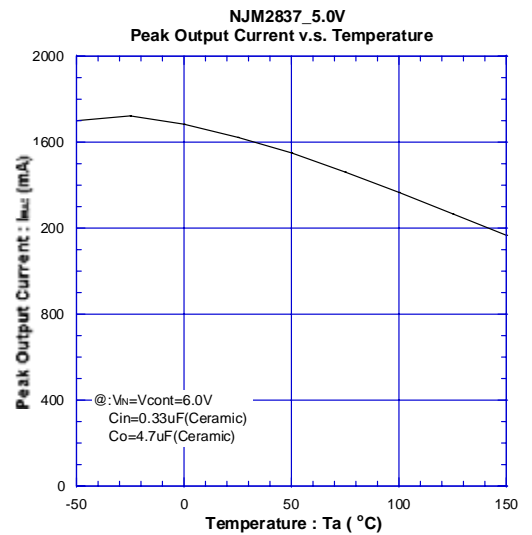

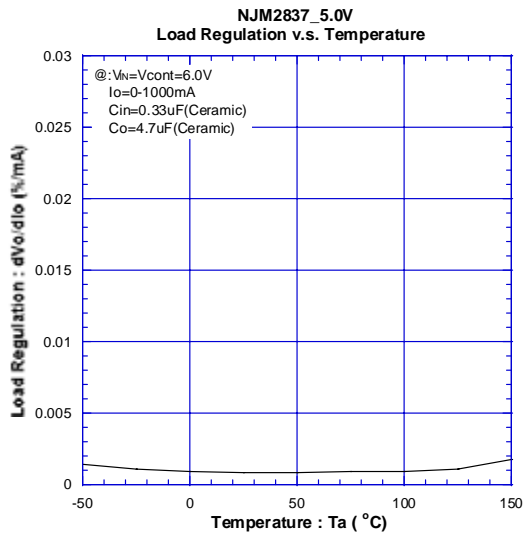

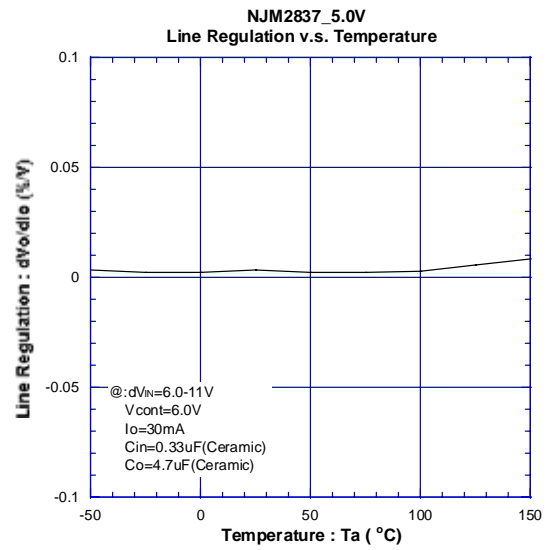

When a regulator is controlled by off ($V_{CONT} < 0.6V$), the reverse current protection circuit functions.
